INVOLUTIONS OF THE SYMMETRIC GROUP AND CONGRUENCE B-ORBITS OF ANTI-SYMMETRIC MATRICES

YONAH CHERNIAVSKY

Abstract. We present the poset of Borel congruence classes of anti-symmetric matrices ordered by containment of closures. We show that there exists a bijection between the set of these classes and the set of involutions of the symmetric group. We give two formulas for the rank function of this poset.

1. Introduction

The remarkable property of the Bruhat decomposition of $GL_n(\mathbb{C})$ (i.e. the decomposition of $GL_n(\mathbb{C})$ into the double cosets $\{B_1\pi B_2\}$ where $\pi \in S_n$, $B_1, B_2 \in \mathbb{B}_n(\mathbb{C})$ – the subgroup of upper-triangular invertible matrices called the Borel subgroup) is that the natural order on double cosets (defined by the containment of closures) leads to the same poset as the combinatorially defined Bruhat order on permutations of S_n (for $\pi, \sigma \in S_n$, $\pi \leqslant \sigma$ if π is a subword of σ with respect to the reduced form in Coxeter generators). L. Renner introduced and developed the beautiful theory of Bruhat decomposition for not necessarily invertible matrices, see [8] and [7]. When the Borel group acts on all the matrices, then the double cosets are in bijection with partial permutations which form a so called rook monoid R_n which is the finite monoid whose elements are the 0-1 matrices with at most one nonzero entry in each row and column. The group of invertible elements of R_n is isomorphic to the symmetric group S_n. Another efficient, combinatorial description of the Bruhat ordering on R_n and a useful, combinatorial formula for the length function on R_n are given by M. Can and L. Renner in [3].

The Bruhat poset of involutions of S_n was first studied by F. Incitti in [4] from purely combinatorial point of view. He proved that this poset is graded, calculated the rank function and also he showed several other important properties of this poset. In [1] we give a geometric interpretation of the poset poset studied by F. Incitti in [4] and its natural generalization considering the action of the Borel subgroup on symmetric matrices by congruence.

In this paper we present another graded poset of involutions of the symmetric group which also has the geometric nature. Denote by $\mathbb{B}_n(\mathbb{C})$ the Borel subgroup of $GL_n(\mathbb{C})$, i.e. the group of invertible upper-triangular $n \times n$ matrices over the complex numbers. Denote by $\mathbb{AS}(n, \mathbb{C})$ the set (which is actually a vector space with respect to standard operations of addition and multiplication by complex scalars, it is a Lie algebra usually denoted as $\mathfrak{so}$ with $[A, B] := AB - BA$) of all complex anti-symmetric $n \times n$ matrices. The congruence action of $B \in \mathbb{B}_n(\mathbb{C})$ on $S \in \mathbb{S}(n, \mathbb{C})$ is defined in the following way: $S \longmapsto B^t S B$. The orbits of this action (to be precisely correct we must say $S \mapsto \left(B^{-1}\right)^t S B^{-1}$ to get indeed a group action) are

The author was supported by the Swiss National Science Foundation.

called the *congruence B-orbits*. It is easy to see that $\mathbb{AS}(n,\mathbb{C})$ is closed under this congruence action.

The main points of this paper are Proposition 2.1, Definition 5.5, Theorem 5.6 and Proposition 6.2. In Proposition 2.1 we show that the orbits of this action may be indexed by involutions of S_n. In Definition 5.5 we introduce the parameter $\mathfrak{A}$ and then in Theorem 5.6 and Proposition 6.2 we give two different formulas for the rank function of the studied poset using the parameter $\mathfrak{A}$. This parameter is similar to the parameter $\mathfrak{D}$ introduced in [1] and it can be seen as a particular case of a certain unified approach to the calculation of the rank function for several "Bruhat-like" posets as we briefly discuss it at the last section of [1].

If we restrict this action on the set of invertible anti-symmetric matrices we get a poset of orbits that is isomorphic to the (reversed) Bruhat poset of involutions of S_n without fixed points which is a subposet of the poset studied by F. Incitti.

2. A bijection between orbits and involutions

The following Proposition 2.1 is somewhat similar to Theorem 3.2 in [9].

Proposition 2.1. *There is a bijection between the set of congruence B-orbits of all anti-symmetric $n\times n$ matrices and the set of all involutions of S_n.*

Proof. Let $A=(a_{ij})_{i,j=1}^{n}\in\mathbb{AS}(n,\mathbb{C})$. We move along the first row of A until we find the first non-zero entry if there exists a non-zero entry in the first row, say $a_{1,j}\neq 0$. Notice that $j>1$ since all the diagonal entries of any anti-symmetric matrix are zeros. Now we can eliminate all non-zero entries in the first row from the right of $a_{1,j}$ multiplying A from the right by appropriate upper-triangular matrix B_1 which differs from the identity matrix only in the j-th row:

$$B_1=\begin{pmatrix} 1 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & 0\\ 0 & 1 & 0 & \cdots & \cdots & \cdots & \cdots & 0\\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots\\ 0 & \cdots & 0 & 1 & \frac{-a_{1,j+1}}{a_{1,j}} & \frac{-a_{1,j+2}}{a_{1,j}} & \cdots & \frac{-a_{1,n}}{a_{1,j}}\\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots\\ 0 & \cdots & \cdots & \cdots & 0 & 1 & 0 & 0\\ 0 & \cdots & \cdots & \cdots & \cdots & 0 & 1 & 0\\ 0 & \cdots & \cdots & \cdots & \cdots & \cdots & 0 & 1 \end{pmatrix}.$$

Similarly we can eliminate all non-zero entries in the j-th column below $a_{1,j}$ multiplying A from the left by appropriate lower-triangular matrix C_1:

$$C_1=\begin{pmatrix} 1 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & 0\\ \frac{-a_{2,j}}{a_{1,j}} & 1 & 0 & \cdots & \cdots & \cdots & \cdots & \cdots & 0\\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots\\ \frac{-a_{j-1,j}}{a_{1,j}} & 0 & \cdots & 1 & 0 & 0 & \cdots & \cdots & 0\\ 0 & \cdots & \cdots & 0 & 1 & 0 & 0 & \cdots & 0\\ \frac{-a_{j+1,j}}{a_{1,j}} & 0 & \cdots & 0 & 0 & 1 & 0 & \cdots & 0\\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots\\ \frac{-a_{n-1,j}}{a_{1,j}} & \cdots & \cdots & \cdots & \cdots & \cdots & 0 & 1 & 0\\ \frac{-a_{n,j}}{a_{1,j}} & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & 0 & 1 \end{pmatrix}.$$

Notice that there must be zero at the position $(j,1)$ in the matrix C_1 because there is zero at the position (j,j) in the matrix A since it is anti-symmetric. The matrix

C_1AB_1 has zeros in the first row to the right from the position $(1,j)$ and in the j-th column below the position $(1,j)$. The matrix

$$C_1B_1^tAB_1C_1^t = \left(B_1C_1^t\right)^t AB_1C_1^t$$

is anti-symmetric, it is in the same congruence B-orbit as A and its entries in the first row and j-th column are zeros except the entry $a_{1,j}$ in the position $(1,j)$, and also all the entries in the j-th row and first column are all zeros except the entry $-a_{1,j}$ in the position $(j,1)$.

Now we do the same elimination process for the second row and so on. At the end we get a monomial anti-symmetric matrix which is in the same congruence B-orbit as A. (Recall that a monomial matrix is a matrix which has at most one non-zero entry in each row and column.) Multiplying by the certain diagonal matrix from both sides we can get the monomial anti-symmetric matrix with only non-zero entries ± 1 and all minuses in the low triangle (below the main diagonal). Each such matrix encodes a the unique involution in the following way: if we have 1 at the position (i,j), (and necessarily -1 at the position (j,i)), this pair of ± 1 corresponds to the transposition (i,j) (the cycle of length 2) which exchanges i and j. Since the matrix is anti-symmetric, if its k-th row is a zero row, then its k-th columns also is a zero column. So, if the k-th row and column are zeros we say that k is a fixed point of the involution that we are constructing. Note that the zero matrix corresponds to the identity element of S_n since everything is fixed. □

We illustrate the above proof with the following example:

Example 2.2. The monomial anti-symmetric matrix $\begin{bmatrix} 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$ corresponds to the involution $\begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 4 & 5 & 3 & 1 & 2 & 6 \end{pmatrix} \in S_6$, which can be written as the product of disjoint transpositions as $(1,4)(2,5)$.

Observation 2.3. The congruence B-orbits of invertible anti-symmetric $2n \times 2n$ matrices can be indexed by involutions of S_{2n} without fixed points.

Proof. It is a particular case of Proposition 2.1. We perform the elimination process described in the proof of Proposition 2.1. Since the initial matrix is invertible, the monomial matrix ± 1's which we get at the end is also invertible and therefore has no zero rows which means that the corresponding involution doesn't have fixed points. □

We end this section with an almost obvious observation:

Observation 2.4. Let X be an anti-symmetric matrix, π a monomial anti-symmetric matrix and $B = (b_{ij})$ invertible upper-triangular matrix such that $X = B^t\pi B$. Then $|Pf(X)| = |b_{11}b_{22}\cdots b_{nn}|$.

3. Partial order on orbits

When an algebraic group acts on a set of matrices, the classical partial order on the set of all orbits is defined as follows:

$$\mathcal{O}_1 \leqslant_{\mathcal{O}} \mathcal{O}_2 \iff \mathcal{O}_1 \subseteq \overline{\mathcal{O}_2}$$

where $\overline{S}$ is the (Zarisski) closure of the set S.

3.1. **Rank-control matrices.**

Definition 3.1. Let $X = (x_{ij})$ be an $n \times m$ matrix. For each $1 \leq k \leq n$ and $1 \leq l \leq m$, denote by $X_{k\ell}$ the upper-left $k \times \ell$ submatrix of X. We denote by $R(X)$ the $n \times m$ matrix whose entries are: $r_{k\ell} = rank\,(X_{k\ell})$ and call it the *rank control matrix* of X.

Remark 3.2. This rank-control matrix is an important tool in [1] and is similar to the one introduced by A. Melnikov [5] when she studied the poset (with respect to the covering relation given in Definition 3) of adjoint B-orbits of certain nilpotent strictly upper-triangular matrices.

The rank control matrix is connected also to the work of F. Incitti [4] where the Bruhat poset of involutions of S_n is studied.

Definition 3.3. Define the following order on $n \times m$ matrices with positive integer entries: Let $P = (p_{ij})$ and $Q = (q_{ij})$ be two such matrices.

Then

$$P \leqslant_{\mathcal{R}} Q \iff p_{ij} \leqslant q_{ij} \text{ for all } i, j\,.$$

The following proposition appears in another form as Theorem 2.1.5 in [2]. Here we identify a permutation with the corresponding permutation matrix.

Proposition 3.4. *Denote by $\leqslant_B$ the Bruhat order of S_n and let $\pi, \sigma \in S_n$. Then*

$$\pi \leqslant_{\mathcal{B}} \sigma \quad \iff \quad R(\pi) \geqslant_{\mathcal{R}} R(\sigma)\,.$$

In other words, the Bruhat order on permutation corresponds to the inverse order of their rank-control matrices.

4. The Poset of Congruence B-Orbits of Anti-Symmetric Matrices

The following easy proposition implies that the rank control matrix is an invariant of a congruence B-orbit.

Proposition 4.1. *Let $X, Y \in GL_n(\mathbb{F})$ be such that $Y = LXB$ for some invertible lower-triangular matrix L and some Borel (i.e. invertible upper-triangular) matrix B. Denote by $X_{k\ell}$ and $Y_{k\ell}$ the upper-left $k \times \ell$ submatrices of X and Y respectively. Then for all $1 \leqslant k, \ell \leqslant n$*

$$rank\,(X_{k\ell}) = rank\,(Y_{k\ell})\ .$$

Here is a direct consequence of Proposition 4.1.

Proposition 4.2. *All the matrices of a fixed congruence B-Orbit have the same rank-control matrix. In other words, if $X \in \mathbb{AS}(n, \mathbb{C})$ and $\mathcal{A}_X$ is the congruence B-orbit of X, then*

$$\mathcal{A}_X = \{S \in \mathbb{AS}(n, \mathbb{C}) \,|\, R(S) = R(X)\}\ .$$

Now we give the proposition which describes the orbit closures. This proposition follows from Theorem 15.31 given by E. Miller and B. Sturmfels, see [6, Chapter 15, page 301]:

Proposition 4.3. *Let π be a partial involution and let $R(\pi)$ be its rank-control matrix. Then*

$$\overline{\mathcal{A}_X} = \{S \in \mathbb{AS}(n,\mathbb{C}) \,|\, R(S) \leqslant_{\mathcal{R}} R(X)\} \,.$$

The next corollary characterizes the order relation of the poset of B-orbits.

Corollary 4.4. *Let $X, Y \in \mathbb{AS}(n,\mathbb{C})$. Then*

$$\mathcal{A}_X \leqslant_{\mathcal{O}} \mathcal{A}_Y \iff R(X) \leqslant_{\mathcal{R}} R(Y)$$

5. The Rank Function of the Poset

Definition 5.1. A poset is called graded (or ranked) if for any two elements x and y of this poset any two maximal chains from x to y have the same length.

Proposition 5.2. *The poset of congruence B-orbits of anti-symmetric matrices (with respect to the order $\leqslant_{\mathcal{O}}$) is a graded poset with the rank function given by the dimension of the closure.*

Corollary 5.3. *The poset of congruence B-orbits of invertible anti-symmetric matrices (with respect to the order $\leqslant_{\mathcal{O}}$) is a graded poset with the rank function given by the dimension of the closure since it is an interval in the poset of congruence B-orbits of all anti-symmetric matrices.*

Remark 5.4. It follows from Observation 2.3 and the results of [1] that the poset of congruence B-orbits of invertible anti-symmetric matrices which is the poset of involutions not having fixed points in the symmetric group is a graded subposet of the (reversed) Bruhat poset, while the whole poset of involutions of the symmetric group with the ordering given by the containment of closures of congruence B-orbits of anti-symmetric matrices is not the Bruhat poset.

Proposition 5.2 is a particular case of the following fact. Let G be a connected, solvable group acting on an irreducible, affine variety X. Suppose that there are a finite number of orbits. Let O be the set of G-orbits on X. For $x, y \in O$ define $x \leqslant y$ if $x \subseteq \overline{y}$. Then O is a graded poset. This fact is given as an exercise in [8] (exercise 12, page 151) and can be proved using the proof of the Theorem of Section 8 of [7]. (Our situation is a particular case of this fact because the Borel group is solvable, the variety of all anti-symmetric matrices is irreducible since it is a vector space and the number of orbits is finite since there are only finitely many involutions in the symmetric group.)

The question is to find an algorithm which calculates the $\dim \overline{\mathcal{A}_X}$ from the involution of the symmetric group which corresponds to the orbit $\mathcal{A}_X$ or from the rank-control matrix $R(X)$. Here we present such an algorithm.

Definition 5.5. Let $X \in \mathbb{AS}(n,\mathbb{C})$ and let $R(X) = (r_{ij})_{i,j=1}^{n}$ be the rank-control matrix of X. Add an extra 0 row to $R(X)$, pushed one place to the left, i.e. assume that $r_{0k} = 0$ for each $0 \leqslant k < n$. Denote

$$\mathfrak{A}(X) = \#\left\{(i,j) \,|\, 1 \leqslant i < j \leqslant n \quad \text{and} \quad r_{ij} = r_{i-1,j-1}\right\}.$$

The parameter $\mathfrak{A}$ counts equalities in the diagonals of the upper triangle of the rank-control matrix and it is very similar to the parameter $\mathfrak{D}$ introduced in [1]. The only difference is that in the case of anti-symmetric matrices we consider the upper triangle without the main diagonal while in the case of the symmetric matrices which is studied in [1] the main diagonal is also considered. This difference is very natural since an anti-symmetric matrix is completely by its upper triangle without the main diagonal which consists of zeros while a symmetric matrix may have anything in its main diagonal. From now on we don't distinguish between an involution π of S_n and the monomial anti-symmetric matrix whose non-zero entries are ± 1 (with minuses in the lower triangle) associated with π by the bijection presented in Proposition 2.1. Notice that when π is a monomial matrix then the entry r_{ij} of the rank-control matrix $R(\pi)$ is the number of nonzero entries of π seen from the position (i,j) when we are looking to the north-west.

Theorem 5.6. *Let $\pi \in S_n$ be an involution. Then*

$$\dim \overline{\mathcal{A}_\pi} = \frac{n^2-n}{2} - \mathfrak{A}(\pi).$$

Proof. We have to explain the following before we begin the proof. By the variety which corresponds to some fragment of the matrix we mean the following: any variety of $n \times n$ matrices is a subset of the vector space $\mathbb{C}^{n^2}$ and the variety which corresponds to a fragment of $n \times n$ matrix is a projection the big variety on the corresponding subspace of $\mathbb{C}^{n^2}$. Denote by V^{kn} the variety which corresponds to

$$\begin{bmatrix}
0 & a_{12} & \cdots & \cdots & a_{1,k} & \cdots & \cdots & a_{1,n-1} & a_{1,n} \\
-a_{12} & 0 & \cdots & \cdots & a_{2,k} & \cdots & \cdots & a_{2,n-1} & a_{2,n} \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
-a_{1,k-1} & -a_{2,k-1} & \cdots & 0 & a_{k-1,k} & \cdots & \cdots & a_{k-1,n-1} & a_{k-1,n} \\
-a_{1,k} & -a_{2,k} & \cdots & \cdots & 0 & \cdots & \cdots & a_{k,n-1} & a_{k,n} \\
-a_{1,k+1} & -a_{2,k+1} & \cdots & \cdots & -a_{k,k+1} & 0 & \cdots & a_{k+1,n-1} & \square \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \square \\
-a_{1,n-1} & -a_{2,n-1} & \cdots & \cdots & \cdots & \cdots & \cdots & 0 & \square \\
-a_{1,n} & -a_{2,n} & \cdots & \cdots & -a_{k,n} & \square & \square & \square & 0
\end{bmatrix}.$$

(For V^{kn} the last non empty entry in the n-th column is in the row number k). Consider also the variety $V^{k-1,n}$ which corresponds to

$$\begin{bmatrix}
0 & \cdots & a_{1,k-1} & \cdots & a_{1,n-1} & a_{1,n} \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
-a_{1,k-1} & \cdots & 0 & \cdots & a_{k-1,n-1} & a_{k-1,n} \\
-a_{1,k} & \cdots & -a_{k-1,k} & \cdots & a_{k,n-1} & \square \\
\cdots & \cdots & \cdots & \cdots & \cdots & \square \\
-a_{1,n-1} & \cdots & \cdots & \cdots & 0 & \square \\
-a_{1,n} & \cdots & -a_{k-1,n} & \square & \square & 0
\end{bmatrix}.$$

Note that since V^{kn} and $V^{k-1,n}$ are projections of the same variety $\overline{\mathcal{A}_\pi}$ and V^{kn} has one more coordinate than $V^{k-1,n}$, there are only two possibilities for their dimensions: $\dim V^{kn} = \dim V^{k-1,n}$ or $\dim V^{kn} = \dim V^{k-1,n} + 1$.

Now we begin the proof. By induction on n. For $n = 1$ the statement is obviously true. Let us consider an $n \times n$ rank-control matrix $R(\pi)$ for some involution $\pi \in S_n$. Its upper-left $(n-1) \times (n-1)$ submatrix is the rank-control matrix $R(\pi_{n-1})$ for

the involution $\pi_{n-1} \in S_{n-1}$ which corresponds to the upper-left $(n-1) \times (n-1)$ submatrix of the matrix π. By the induction hypothesis,

$$\dim \overline{\mathcal{A}_{\pi_{n-1}}} = \frac{(n-1)^2 - (n-1)}{2} - \mathfrak{A}(\pi_{n-1}) .$$

Now we add the n-th column to the partial involution matrix (the n-th does not provide any new information because we deal with the anti-symmetric matrices) and consider the n-th column of $R(\pi)$. (We also add the n-th row but since our matrices are anti-symmetric it suffices to understand only what happens to the dimension when we add the n-th column.) We added $n-1$ new coordinates (since there must be zero at the position (n,n)) to the variety $\overline{\mathcal{A}_{\pi_{n-1}}}$ and we have to show that

$$\dim \overline{\mathcal{A}_{\pi}} = \dim \overline{\mathcal{A}_{\pi_{n-1}}} + n - 1 - \#\{(i,n) \,|\, 1 \leqslant i \leqslant n-1 \text{ and } r_{in} = r_{i-1,n-1}\} , \ (*)$$

i.e. not all the $n-1$ coordinates that we added make the dimension greater but only those of them for which there is an inequality in the corresponding place of the certain diagonal of the rank-control matrix. The equality $(*)$ implies the statement of our theorem since $\frac{(n-1)^2-(n-1)}{2} + n - 1 = \frac{n^2-n}{2}$ and

$$\mathfrak{A}(\pi) = \mathfrak{A}(\pi_{n-1}) + \#\{(i,n) \,|\, 1 \leqslant i \leqslant n-1 \quad \text{and} \quad r_{in} = r_{i-1,n-1}\} .$$

Obviously, if $r_{1,n} = 0$, then $a_{1,n} = 0$ for any $A = (a_{ij})_{i,j=1}^{n} \in \overline{\mathcal{A}_{\pi}}$, this itself is a polynomial equation which makes the dimension lower by 1, while if $r_{1,n} = 1$ it means that the rank of the first row is maximal and therefore, no equation. (In other words, the dimension of the variety V^{1n} which corresponds to $\begin{bmatrix} 0 & a_{12} & \cdots & a_{1,n-1} & a_{1,n} \\ -a_{12} & 0 & \cdots & a_{2,n-1} & \square \\ \cdots & \cdots & \cdots & \cdots & \square \\ -a_{1,n-1} & -a_{2.n-1} & \cdots & 0 & \square \\ -a_{1,n} & \square & \square & \square & 0 \end{bmatrix}$ is greater by one than the of the variety V^{0n} which corresponds to $\begin{bmatrix} 0 & a_{12} & \cdots & a_{1,n-1} \\ -a_{12} & 0 & \cdots & a_{2,n-1} \\ \cdots & \cdots & \cdots & \cdots \\ -a_{1,n-2} & -a_{2,n-2} & \cdots & a_{n-2,n-1} \\ -a_{1,n-1} & -a_{2,n-1} & \cdots & 0 \end{bmatrix}$ when $r_{1,n} = 1$ and they have equal dimensions when $r_{1,n} = 0$.) Now move down along the n-th column of $R(\pi)$. Again by induction, this time the induction is on the number of row k, assume that for each $1 \leqslant i \leqslant k-1$ the dimensions of V^{in} and $V^{i-1,n}$ ar equal iff $r_{i-1,n-1} = r_{i,n}$ and $\dim V^{in} = \dim V^{i-1,n} + 1$ iff $r_{i-1,n-1} < r_{i,n}$. First, let $r_{k-1,n-1} = r_{k,n} = c$. Consider a matrix $A = (a_{ij})_{i,j=1}^{n} \in \overline{\mathcal{A}_{\pi}}$ and consider its upper-left $(k-1) \times (n-1)$ submatrix $\begin{bmatrix} 0 & a_{12} & \cdots & \cdots & a_{1,n-1} \\ -a_{12} & 0 & \cdots & \cdots & a_{2,n-1} \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ -a_{1,k-1} & -a_{2,k-1} & \cdots & \cdots & a_{k-1,n-1} \end{bmatrix}$. Using the notation introduced in Proposition 4.1, we denote this submatrix as $A_{k-1,n-1}$. If $c = 0$, then $rank A_{kn} = 0$, so A_{kn} is a zero matrix and $\dim V^{in} = \dim V^{i-1,n} = 0$. Let $c \neq 0$. Since $rank\,(A_{k-1,n-1}) = c$, we can take c linearly independent columns

$\begin{bmatrix} a_{1,j_1} \\ a_{2,j_1} \\ \cdots \\ a_{k-1,j_1} \end{bmatrix}$, ... , $\begin{bmatrix} a_{1,j_c} \\ a_{2,j_c} \\ \cdots \\ a_{k-1,j_c} \end{bmatrix}$ which span its column space. Now take only linearly independent rows of the $(k-1)\times c$ matrix $\begin{bmatrix} a_{1,j_1} & \cdots & a_{1,j_c} \\ a_{2,j_1} & \cdots & a_{2,j_c} \\ \cdots & \cdots & \cdots \\ a_{k-1,j_1} & \cdots & a_{k-1,j_c} \end{bmatrix}$ to get a nonsingular $c \times c$ matrix $\begin{bmatrix} a_{i_1,j_1} & \cdots & a_{i_1,j_c} \\ a_{i_2,j_1} & \cdots & a_{i_2,j_c} \\ \cdots & \cdots & \cdots \\ a_{i_c,j_1} & \cdots & a_{i_c,j_c} \end{bmatrix}$. The equality $r_{k-1,n-1} = r_{k,n} = c \leqslant k-1$ implies that any $(c+1) \times (c+1)$ minor of the matrix A_{kn} is zero, in particular $\det \begin{bmatrix} a_{i_1,j_1} & \cdots & a_{i_1,j_c} & a_{i_1,n} \\ a_{i_2,j_1} & \cdots & a_{i_2,j_c} & a_{i_2,n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{i_c,j_1} & \cdots & a_{i_c,j_c} & a_{i_c,n} \\ a_{k,j_1} & \cdots & a_{k,j_c} & a_{k,n} \end{bmatrix} = 0$, which is a polynomial equation. This equation is algebraically independent of the similar equations obtained for $1 \leqslant i \leqslant k-1$ because it involves the "new" variable – the entry $a_{k,n}$. It indeed involves the entry $a_{k,n}$ since $\det \begin{bmatrix} a_{i_1,j_1} & \cdots & a_{i_1,j_c} \\ a_{i_2,j_1} & \cdots & a_{i_2,j_c} \\ \cdots & \cdots & \cdots \\ a_{i_c,j_1} & \cdots & a_{i_c,j_c} \end{bmatrix} \neq 0$. This equation means that the variable $a_{k,n}$ is not independent of the coordinates of the variety $V^{k-1,n}$, and therefore $\dim V^{k-1,n} = \dim V^{kn}$.

Now let $r_{k-1,n-1} < r_{k,n} = c$, and we have to show that in this case the variable a_{nk} is independent of the coordinates of $V^{k-1,n}$, in other words, we have to show that there is no new equation. Consider the fragment $\begin{bmatrix} r_{k-1,n-1} & r_{k-1,n} \\ r_{k-1,n} & r_{k,n} \end{bmatrix}$. There are four possible cases:

$$\begin{bmatrix} r_{k-1,n-1} & r_{k-1,n} \\ r_{k-1,n} & r_{k,n} \end{bmatrix} = \begin{bmatrix} c-1 & c-1 \\ c-1 & c \end{bmatrix} \quad \text{or} \quad \begin{bmatrix} c-2 & c-1 \\ c-1 & c \end{bmatrix} \quad \text{or}$$
$$\begin{bmatrix} c-1 & c \\ c-1 & c \end{bmatrix} \quad \text{or} \quad \begin{bmatrix} c-1 & c-1 \\ c & c \end{bmatrix} .$$

The equality $r_{k,n} = c$ implies that each $(c+1)\times(c+1)$ minor of A_{kn} is equal to zero, but we shall see that each such equation is not new, i.e. it is implied by the equality $r_{k,n-1} = c-1$ or by the equality $r_{k-1,n} = c-1$. In the first three of above four cases we decompose the $(c+1)\times(c+1)$ determinant $\det \begin{bmatrix} \cdots & \cdots \\ \cdots & a_{k,n} \end{bmatrix}$ using the last column. Since in all these cases $r_{k,n-1} = c-1$, each $c\times c$ minor of this decomposition (i.e. each $c \times c$ minor of $A_{k,n-1}$) is zero and therefore, this determinant is zero. In the fourth case we get the same if we decompose the determinant using its last row instead of the last column: since $r_{k-1,n} = c-1$, all the $c \times c$ minors of this decomposition (i.e. all $c\times c$ minor of $A_{k-1,n}$) are zeros and thus, our $(c+1)\times(c+1)$ determinant equals to zero. So there is no algebraic dependence between a_{kn} and

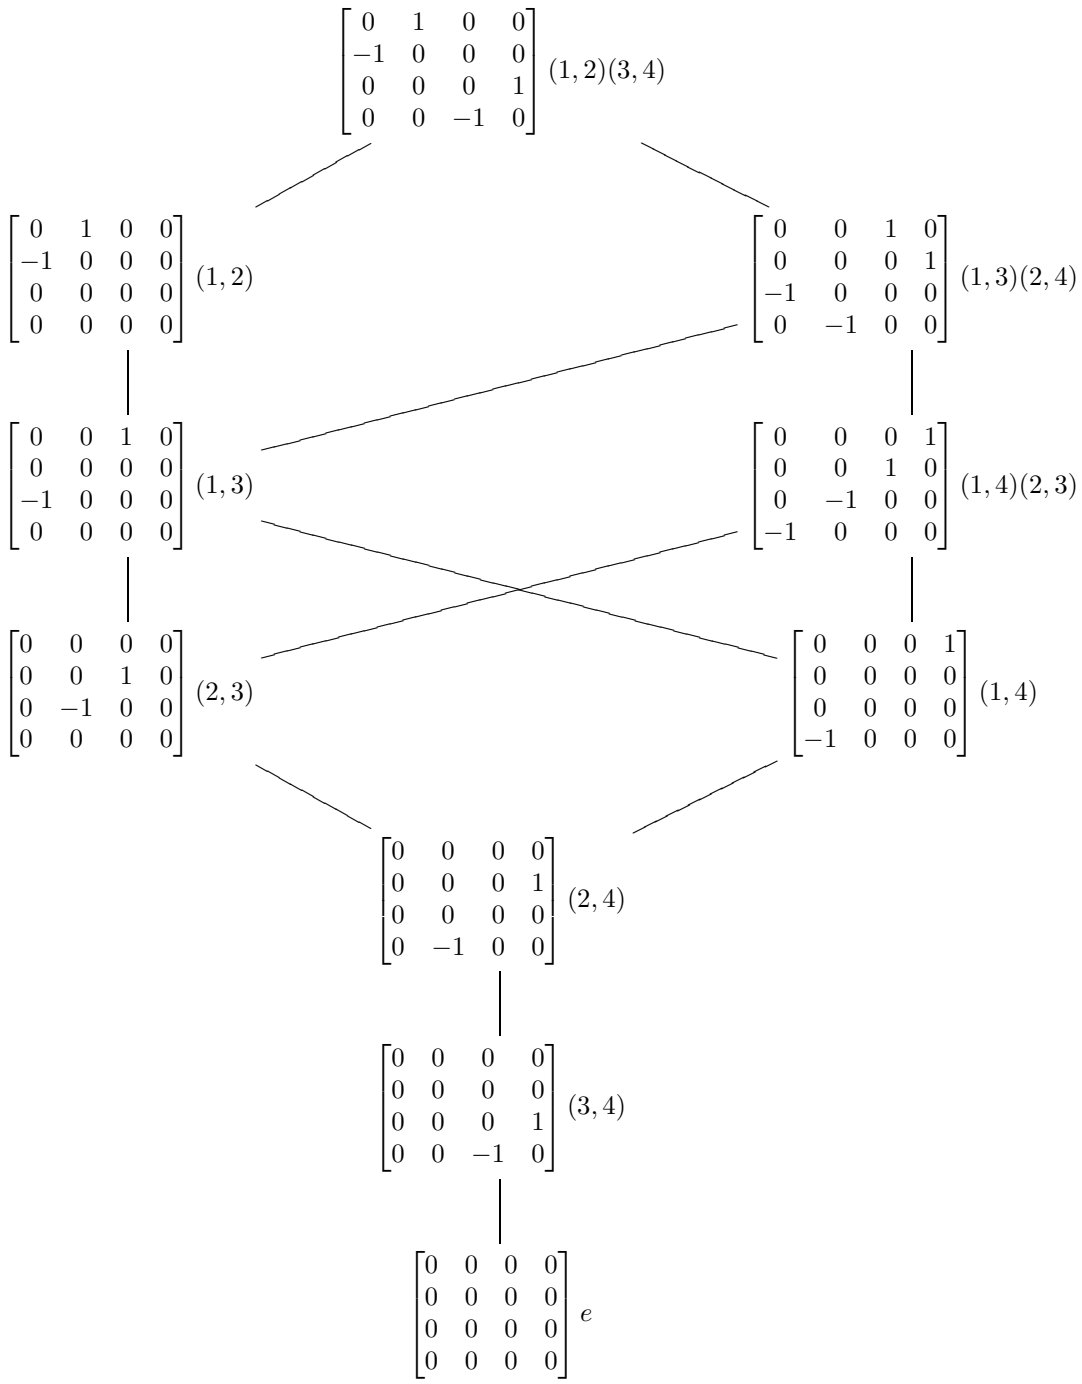
the coordinates of $V^{k-1,n}$. Therefore, $\dim V^{kn} = \dim V^{k-1,n} + 1$. The proof is completed. □

Notice that the number $\frac{n^2-n}{2}$ is the dimension of the vector space of $n \times n$ anti-symmetric matrices.

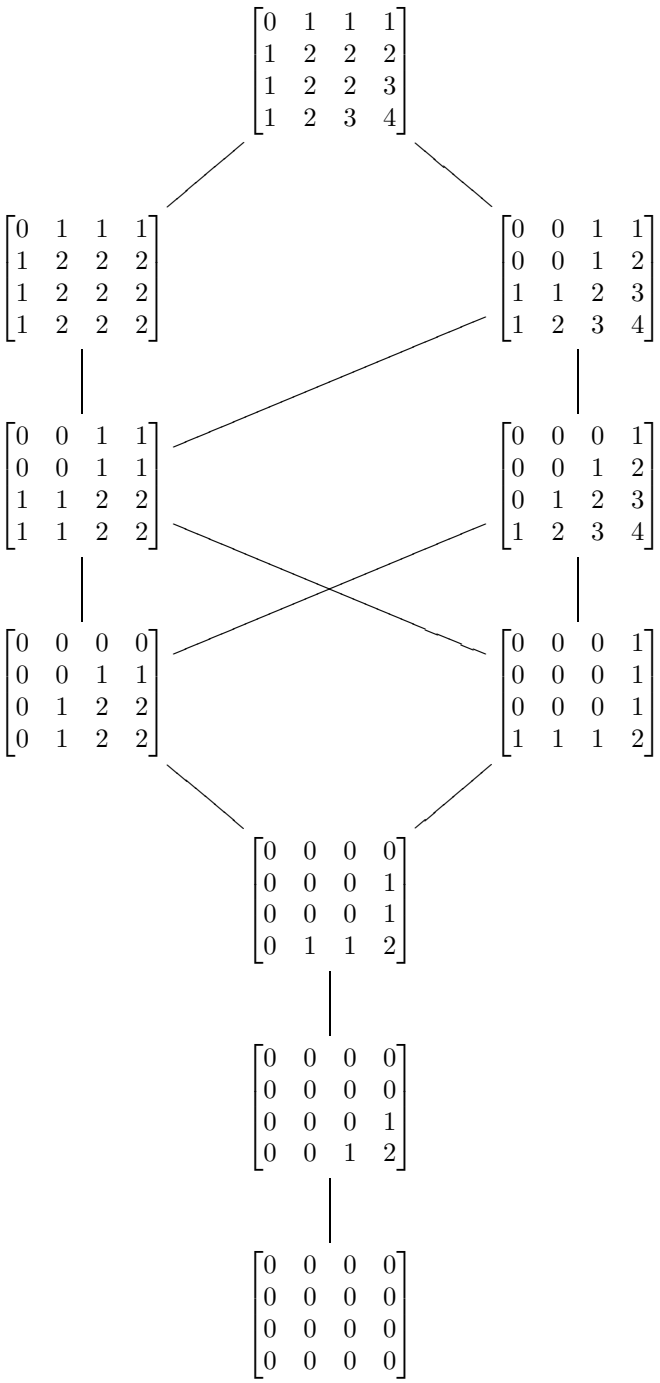
To illustrate Theorem 5.6 let us consider the second (from the top) level in the example given below. The diagonals (with added zeros at the beginning) of the upper triangle of the rank-control matrix $R_1 = \begin{bmatrix} 0 & 1 & 1 & 1 \\ 1 & 2 & 2 & 2 \\ 1 & 2 & 2 & 2 \\ 1 & 2 & 2 & 2 \end{bmatrix}$ are: (0 1 2 2), (0 1 2) and (0 1). We see that there is only one equality in the first of them (we have twice 2) and therefore $\mathfrak{A}(R_1) = 1$. The diagonals (with added zeros at the beginning) of the upper triangle of the rank-control matrix $R_2 = \begin{bmatrix} 0 & 0 & 1 & 1 \\ 0 & 0 & 1 & 2 \\ 1 & 1 & 2 & 3 \\ 1 & 2 & 3 & 4 \end{bmatrix}$ are: (0 0 1 3), (0 1 2) and (0 1). We see that there is only one equality in the first of them (we have twice 0) and therefore $\mathfrak{A}(R_2) = 1$. The fact that $\mathfrak{A}(R_1) = \mathfrak{A}(R_2) = 1$ means that the matrices R_1 and R_2 are both at the first from the top level in the poset.

5.1. **An example.** Here we present this poset for $n = 4$. In the first diagram we have the monomial matrices which are the representatives of the orbits and corresponding involutions of S_4. In the second diagram there are rank-control

matrices.



$\begin{bmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{bmatrix}$ $(1,2)(3,4)$
$\begin{bmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ $(1,2)$
$\begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix}$ $(1,3)(2,4)$
$\begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ $(1,3)$
$\begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{bmatrix}$ $(1,4)(2,3)$
$\begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ $(2,3)$
$\begin{bmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{bmatrix}$ $(1,4)$
$\begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix}$ $(2,4)$
$\begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{bmatrix}$ $(3,4)$
$\begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ e



6. Another formula for the rank function.

In this section, as before, we also don't distinguish between an involution $\pi \in S_n$ and the monomial anti-symmetric matrix (with minuses in the lower triangle) associated to π by the bijection presented in Proposition 2.1.

Definition 6.1. Let $\pi \in S_n$ be an involution. It is always possible to write it as product of disjoint transpositions

$$\pi = (i_1, j_1)\,(i_2, j_2)\cdots(i_k, j_k)$$

in such a way that for all $1 \leqslant t \leqslant k$, $i_t < j_t$ and $i_1 < i_2 < \cdots < i_k$. Let us call it "the canonic form".

Denote by $\mathfrak{I}(\pi)$ the **number of inversions** in the word $i_1 j_1 i_2 j_2 \cdots i_k j_k$.

Proposition 6.2. *Let $\pi \in S_n$ be an involution. Then*

$$\mathfrak{A}(\pi) = \mathfrak{I}(\pi) + \sum_{a\,:\,\pi(a)=a} (n-a)\,.$$

Proof. By induction on n. Denote by π_{n+1} some involution of S_{n+1} and also the monomial anti-symmetric matrix which corresponds to this involution. Denote by π_n the involution of S_n which corresponds to the upper-left $n \times n$ block of the matrix π_{n+1}. For π_n the statement is true by the induction hypothesis. Now we have to consider two cases:

Case1. The number $n+1$ is a fixed point of the involution π_{n+1} or in other words the n-th row and column of the matrix π_{n+1} consist only of zeros. In this case we obviously have $\mathfrak{I}(\pi_{n+1}) = \mathfrak{I}(\pi_n)$ and each fixed of π_n is also a fixed point of π_{n+1}. It means that each fixed point of π_n contributes an additional 1 (with comparison with $\mathfrak{A}(\pi_n)$) to $\mathfrak{A}(\pi_{n+1}$. So,

$$\begin{aligned}
\mathfrak{A}(\pi_{n+1}) &= \mathfrak{A}(\pi_n) + \sum_{a\,:\,\pi_n(a)=a} 1 = \\
&= \mathfrak{I}(\pi_n) + \sum_{a\,:\,\pi_n(a)=a} (n-a) + \sum_{a\,:\,\pi_n(a)=a} 1 = \\
&= \mathfrak{I}(\pi_{n+1}) + \sum_{a\,:\,\pi_{n+1}(a)=a} (n+1-a)\,.
\end{aligned}$$

Case2. The number $n+1$ is not a fixed point of the involution π_{n+1}. It means that the canonic form of π_{n+1} is

$$\pi_{n+1} = (i_1, j_1)\cdots(i, n+1)\cdots(i_k, j_k)$$

for some i or in other words the matrix π_{n+1} has 1 at the position $(i, n+1)$ (and,of course, it also has -1 at the position $(n+1, i)$). We must show that

$$\mathfrak{A}(\pi_{n+1}) = \mathfrak{I}(\pi_{n+1}) + \sum_{a\,:\,\pi_{n+1}(a)=a} (n+1-a)\,.$$

By obvious observation

$$\mathfrak{A}(\pi_{n+1}) = \mathfrak{A}(\pi_n) + \#\left\{a\,:\,\pi_n(a) = a\,\&\,a < i\right\}.$$

By induction hypothesis $\mathfrak{A}(\pi_n) = \mathfrak{I}(\pi_n) + \sum_{a\,:\,\pi_n(a)=a}(n-a)$ and so

$$\mathfrak{A}(\pi_{n+1}) = \mathfrak{I}(\pi_n) + \sum_{a\,:\,\pi_n(a)=a} (n-a) + \#\left\{a\,:\,\pi_n(a) = a\,\&\,a < i\right\}. \qquad (*)$$

Now, by direct calculation we have

$$\begin{aligned}\mathfrak{I}(\pi_{n+1}) + \sum_{a\,:\,\pi_{n+1}(a)=a} (n+1-a) &= \mathfrak{I}(\pi_n) + \#\left\{(i_t,j_t)\,:\, i_t<i\,\&\,j_t>i\right\} + \\ &+ 2\cdot\#\left\{(i_t,j_t)\,:\, i_t>i\right\} + \sum_{a\,:\,\pi_{n+1}(a)=a} (n-a) + \#\left\{a\,:\,\pi_{n+1}(a)=a\right\} = \\ &= \mathfrak{I}(\pi_n) + \#\left\{(i_t,j_t)\,:\, i_t<i\,\&\,j_t>i\right\} + 2\cdot\#\left\{(i_t,j_t)\,:\, i_t>i\right\} + \\ &+ \sum_{a\,:\,\pi_n(a)=a} (n-a) - (n-i) + \#\left\{a\,:\,\pi_{n+1}(a)=a\right\} \qquad (**)\end{aligned}$$

Comparing $(*)$ and $(**)$ we see that suffices to show that

$$\begin{aligned}\#\left\{a\,:\,\pi_n(a)=a\,\&\,a<i\right\} = \#\left\{(i_t,j_t)\,:\, i_t<i\,\&\,j_t>i\right\} + 2\cdot\#\left\{(i_t,j_t)\,:\, i_t>i\right\} + \\ + \#\left\{a\,:\,\pi_{n+1}(a)=a\right\} - (n-i)\end{aligned}$$

which is obviously equivalent to the equality

$$\begin{aligned}n-i = &\#\left\{(i_t,j_t)\,:\, i_t<i\,\&\,j_t>i\right\} + 2\cdot\#\left\{(i_t,j_t)\,:\, i_t>i\right\} + \\ &+ \#\left\{a\,:\,\pi_n(a)=a\,\&\,a>i\right\},\end{aligned}$$

which is indeed true since the number

$$\#\left\{(i_t,j_t)\,:\, i_t<i\,\&\,j_t>i\right\} + 2\cdot\#\left\{(i_t,j_t)\,:\, i_t>i\right\}$$

is the number of all numbers greater than i which are not fixed by π_{n+1} while the number $\#\left\{a\,:\,\pi_n(a)=a\,\&\,a>i\right\}$ is the number of all numbers greater than i which are fixed by π_{n+1}. So the sum of these two numbers is indeed $n-i$. □

7. The final remark

It follows from Observation 2.3 and the results of [1] that the poset of congruence B-orbits of invertible anti-symmetric matrices which is the poset of involutions not having fixed points in the symmetric group is a graded subposet of the (reversed) Bruhat poset of involutions of the symmetric group studied by F. Incitti in [4], while the whole poset of involutions of the symmetric group with the ordering given by the containment of closures of congruence B-orbits of anti-symmetric matrices is not the Bruhat poset. The same is true not only for the set of involutions without fixed points but for any set of involutions with prescribed support (or in other words fixed set of fixed points).

Notice that the subposet of involutions with prescribed support is not an interval in the Bruhat poset of involutions of the symmetric group while it is an interval in the poset of involutions of the symmetric group introduced in this paper.

Acknowledgements. I would like to express the special gratitude to Prof. Lex Renner for the very useful information about the Bruhat poset and answering the numerous questions. This work was done when I was a postdoc at the Department of Mathematics at the University of Geneva and I would like to thank the department and especially Prof. Tatiana Smirnova-Nagnibeda for the hospitality and discussion. I am grateful to the Swiss National Science Foundation for the financial support. I am grateful to Prof. Ron M. Adin, Dr. Eli Bagno, Dr. Anna Melnikov and Prof. Yuval Roichman for the helpful discussions.
